19th French-German-Swiss Conference on Optimization, Nice, September 18, 2019

$$\begin{array}{ll} \underset{w \in \mathbb{R}^{n_w}}{\text{minimize}} & \phi_0(F_0(w))\\ \text{subject to} & F_i(w) \in \Omega_i \quad i = 1, \dots, m,\\ & G(w) = 0 \end{array}$$

Assumptions:

- twice continuously differentiable functions  $G : \mathbb{R}^{n_w} \to \mathbb{R}^{n_g}$  and  $F_i : \mathbb{R}^{n_w} \to \mathbb{R}^{n_{F_i}}$  for  $i = 0, 1, \dots, m$ .
- outer function  $\phi_0 : \mathbb{R}^{n_{F_0}} \to \mathbb{R}$  convex.
- sets  $\Omega_i \subset \mathbb{R}^{n_{F_i}}$  convex for  $i = 1, \dots, m$ , (possibly  $z \in \Omega_i \Leftrightarrow \phi_i(z) \leq 0$  with smooth convex  $\phi_i$ )

$$\begin{array}{ll} \underset{w \in \mathbb{R}^{n_w}}{\text{minimize}} & \phi_0(F_0(w))\\ \text{subject to} & F_i(w) \in \Omega_i \quad i = 1, \dots, m,\\ & G(w) = 0 \end{array}$$

Assumptions:

• twice continuously differentiable functions  $G : \mathbb{R}^{n_w} \to \mathbb{R}^{n_g}$  and  $F_i : \mathbb{R}^{n_w} \to \mathbb{R}^{n_{F_i}}$  for  $i = 0, 1, \dots, m$ .

• outer function  $\phi_0 : \mathbb{R}^{n_{F_0}} \to \mathbb{R}$  convex.

sets 
$$\Omega_i \subset \mathbb{R}^{n_{F_i}}$$
 convex for  $i = 1, \dots, m$ ,  
(possibly  $z \in \Omega_i \Leftrightarrow \phi_i(z) \leq 0$  with smooth convex  $\phi_i$ )

Idea:

exploit convex substructure via iterative convex approximations.

# Why is this class of problems and algorithms interesting?

- some nonlinear programming (NLP) problems have nonsmooth convex constraints which cannot be treated by standard NLP solvers
- there exist many reliable and efficient convex optimization solvers

Some application areas:

- nonlinear matrix inequalities for reduced order controller design [Fares, Noll, Apkarian 2002; Tran-Dinh et al. 2012]
- ellipsoidal terminal regions in nonlinear model predictive control [Chen and Allgöwer 1998; Verschueren 2016]
- robustified inequalities in nonlinear optimization [Nagy and Braatz 2003; D., Bock, Kostina 2006]
- tube-following optimal control problems [Van Duijkeren, 2019]
- non-smooth composite minimization [Lewis and Wright 2016]
- deep neural network training with convex loss functions [Schraudolph 2002; Martens 2016]

◆□ → < 部 → < 差 → < 差 → 差 → ○ < ○ 5/42

Iterative convex approximation methods such as sequential convex programming (SCP) have only linear convergence in general.

- Iterative convex approximation methods such as sequential convex programming (SCP) have only linear convergence in general.
- The rate of convergence cannot be improved to superlinear by any bounded semi-definite Hessian approximation [D., Jarre, Vogelbusch 2006]

Simple TR example problem with dominant nonconvexities in objective:

$$\begin{array}{ll} \text{minimize} & -w_1^2 - (1 - w_2)^2 \\ w \in \mathbb{R}^2 & \\ \text{subject to} & \|w\|_2 \le 1 \end{array}$$

- Iterative convex approximation methods such as sequential convex programming (SCP) have only linear convergence in general.
- The rate of convergence cannot be improved to superlinear by any bounded semi-definite Hessian approximation [D., Jarre, Vogelbusch 2006]

Simple TR example problem with dominant nonconvexities in objective:

$$\begin{array}{ll} \underset{w \in \mathbb{R}^2}{\text{minimize}} & -w_1^2 - (1 - w_2)^2 \\ \text{subject to} & \|w\|_2 \le 1 \end{array}$$

But: many real-world problems have dominant convexities and SCP often shows fast linear convergence in practice.

- Iterative convex approximation methods such as sequential convex programming (SCP) have only linear convergence in general.
- The rate of convergence cannot be improved to superlinear by any bounded semi-definite Hessian approximation [D., Jarre, Vogelbusch 2006]

Simple TR example problem with dominant nonconvexities in objective:

$$\begin{array}{ll} \underset{w \in \mathbb{R}^2}{\text{minimize}} & -w_1^2 - (1 - w_2)^2 \\ \text{subject to} & \|w\|_2 \le 1 \end{array}$$

But: many real-world problems have dominant convexities and SCP often shows fast linear convergence in practice. How fast?

# Overview

## Smooth unconstrained problems

- Sequential Convex Programming (SCP)
- Generalized Gauss-Newton (GGN)
- Local convergence analysis
- Desirable divergence
- Illustrative example in CasADi
- Constrained problems
  - Sequential Convex Programming (SCP)
  - Sequential Linear Programming (SLP)
  - Constrained Generalized Gauss-Newton (CGGN)
  - Sequential Convex Quadratic Programming (SCQP)
- Recent Progress in Dynamic Optimization and Applications

Unconstrained minimization of "convex over nonlinear" function:

Assumptions:

- Inner function  $F:\mathbb{R}^n\to\mathbb{R}^N$  of class  $C^3$
- Outer function  $\phi:\mathbb{R}^N\to\mathbb{R}$  of class  $C^3$  and convex

Remark:

 $F,\phi,f\in C^3$  avoids technical details that would obfuscate main results.

Matrix inequality  $A \succ B$  for  $A, B \in \mathbb{S}^n$  (symmetric matrices)

Gradient  $\nabla f(w) \in \mathbb{R}^n$  and Hessian  $\nabla^2 f(w) \in \mathbb{S}^n$  for  $f : \mathbb{R}^n \to \mathbb{R}$ 

Jacobian  $J(w) := \frac{\partial F}{\partial w}(w) \in \mathbb{R}^{N \times n}$  for  $F : \mathbb{R}^n \to \mathbb{R}^N$ 

Linearization (first order Taylor series) at  $\bar{w} \in \mathbb{R}^n$ :

$$F_{\rm lin}(w; \bar{w}) := F(\bar{w}) + J(\bar{w}) (w - \bar{w})$$

Big  $O(\cdot)$  notation: e.g.  $F_{\text{lin}}(w; \bar{w}) = F(w) + O(||w - \bar{w}||^2)$ 

Note: gradient of  $f(w) = \phi(F(w))$  is  $\nabla f(w) = J(w)^{\top} \nabla \phi(F(w))$ 

Starting at  $w_0 \in \mathbb{R}^n$  we generate sequence  $\ldots, w_k, w_{k+1}, \ldots$ 

by obtaining  $w_{k+1}$  as solution of convex subproblem at  $\bar{w} = w_k$ :

$$\begin{array}{ll}
\text{minimize} \\
w \in \mathbb{R}^n \\
 & \underbrace{\phi\left(F_{\text{lin}}(w;\bar{w})\right)}_{=:f_{\text{SCP}}(w;\bar{w})}
\end{array} \tag{1}$$

(requires possibly expensive calls of a convex optimization solver)

Observation:  $f_{SCP}(w; \bar{w}) = f(w) + O(||w - \bar{w}||^2)$ Corollary:  $\nabla f(\bar{w}) = 0 \iff \bar{w}$  fixed point of SCP

(if subproblems (1) have unique solutions)

# **Tutorial Example**

Regard 
$$F(w) = \begin{bmatrix} \sin(w) \\ \exp(w) - 2 \end{bmatrix}$$
 and  $\phi(z) = z_1^4 + z_2^2$   
Linearization:  $F_{\text{lin}}(w; \bar{w}) = \begin{bmatrix} \sin(\bar{w}) + \cos(\bar{w})(w - \bar{w}) \\ \exp(\bar{w}) - 2 + \exp(\bar{w})(w - \bar{w}) \end{bmatrix}$   
SCP objective:  
 $f_{\text{SCP}}(w; \bar{w}) = (\sin(\bar{w}) + \cos(\bar{w})(w - \bar{w}))^4 + w$ 

Fig.:  $f(w) = \phi(F(w))$  (solid) and  $f_{\rm SCP}(w; \bar{w})$  (dashed) for  $\bar{w} = 0$ 

With quadratic  $\phi(z) = \frac{1}{2} ||z||_2^2 = \frac{1}{2} z^{\top} z$ , SCP subproblems become

$$\min_{w \in \mathbb{R}^n} \quad \frac{1}{2} \|F(w_k) + J(w_k)(w - w_k)\|_2^2$$
 (2)

(ロ) (部) (目) (日) (日) (の)

If  $\operatorname{rank}(J) = n$  this is uniquely solvable, giving

$$w_{k+1} = w_k - \left(\underbrace{J(w_k)^{\top} J(w_k)}_{=:B_{\rm GN}(w_k)}\right)^{-1} \underbrace{J(w_k)^{\top} F(w_k)}_{=\nabla f(w_k)}$$

SCP applied to LS = Newton method with "Gauss-Newton Hessian"

 $B_{\rm GN}(w) \approx \nabla^2 f(w)$ 

# Method 2: Generalized Gauss-Newton cf. [Schraudolph 2002]

For general convex 
$$\phi(\cdot)$$
 we have for  $f(w) = \phi(F(w))$   

$$\nabla^2 f(w) = \underbrace{J(w)^\top \nabla^2 \phi(F(w)) \ J(w)}_{=:B_{\text{GGN}}(w)} + \underbrace{\sum_{j=1}^N \nabla^2 F_j(w) \ \nabla_{z_j} \phi(F(w))}_{=:E_{\text{GGN}}(w)}$$
"GGN Hessian" "Error matrix"

# Method 2: Generalized Gauss-Newton cf. [Schraudolph 2002]

For general convex 
$$\phi(\cdot)$$
 we have for  $f(w) = \phi(F(w))$   

$$\nabla^2 f(w) = \underbrace{J(w)^\top \nabla^2 \phi(F(w)) J(w)}_{=:B_{\text{GGN}}(w)} + \underbrace{\sum_{j=1}^N \nabla^2 F_j(w) \nabla_{z_j} \phi(F(w))}_{=:E_{\text{GGN}}(w)}$$
"GGN Hessian" "Error matrix"

Generalized Gauss-Newton (GGN) method iterates according to

$$w_{k+1} = w_k - B_{\text{GGN}}(w)^{-1} \nabla f(w_k)$$

# Method 2: Generalized Gauss-Newton cf. [Schraudolph 2002]

For general convex 
$$\phi(\cdot)$$
 we have for  $f(w) = \phi(F(w))$   

$$\nabla^2 f(w) = \underbrace{J(w)^\top \nabla^2 \phi(F(w)) J(w)}_{=:B_{\text{GGN}}(w)} + \underbrace{\sum_{j=1}^N \nabla^2 F_j(w) \nabla_{z_j} \phi(F(w))}_{=:E_{\text{GGN}}(w)}$$
"GGN Hessian" "Error matrix"

Generalized Gauss-Newton (GGN) method iterates according to

$$w_{k+1} = w_k - B_{\text{GGN}}(w)^{-1} \nabla f(w_k)$$

Note: GGN solves convex quadratic subproblems

$$\min_{w \in \mathbb{R}^n} \underbrace{f(w_k) + \nabla f(w_k)^\top (w - w_k) + \frac{1}{2} (w - w_k)^\top B_{\text{GGN}}(w_k) (w - w_k)}_{=:f_{\text{GGN}}(w;w_k)}$$

# Tutorial Example: GGN and SCP

Regard again 
$$F(w) = \begin{bmatrix} \sin(w) \\ \exp(w) - 2 \end{bmatrix}$$
 and  $\phi(z) = z_1^4 + z_2^2$   
Jacobian:  
$$J(\bar{w}) = \begin{bmatrix} \cos(\bar{w}) \\ \exp(\bar{w}) \end{bmatrix}$$

GGN objective at  $\bar{w} = 0$ :

Figure shows f (solid),  $f_{SCP}$  (dashed) and  $f_{GGN}$  (dash dotted)

# Differences and Similarities of SCP and GGN

- both SCP and GGN generalize the Gauss-Newton method (and become equal to it when applied to nonlinear least squares)
- both iteratively solve convex optimization problems
- GGN only solves a positive definite linear system per iteration
- SCP solves a full convex problem per iteration (5-30x slower)
- SCP often less sensitive to initialization
- both are NOT second order methods
- both converge linearly with the same rate (details follow)

# Local Convergence Analysis for SCP and GGN

 $\begin{aligned} & \text{Recall:} \\ & f_{\text{SCP}}(w; \bar{w}) = \phi \left( F_{\text{lin}}(w; \bar{w}) \right) \\ & f_{\text{GGN}}(w; \bar{w}) = f(\bar{w}) + \nabla f(\bar{w})^{\mathsf{T}} (w - \bar{w}) + \frac{1}{2} (w - \bar{w})^{\mathsf{T}} B_{\text{GGN}}(\bar{w}) (w - \bar{w}) \\ & \nabla_w f_{\text{SCP}}(\bar{w}; \bar{w}) = \nabla_w f_{\text{GGN}}(\bar{w}; \bar{w}) = \nabla f(\bar{w}) \end{aligned}$ 

Lemma 1 (Equality of SCP and GGN up to Second Order)

 $f_{\rm SCP}(w; \bar{w}) = f_{\rm GGN}(w; \bar{w}) + O(||w - \bar{w}||^3)$ 

Proof:  $\nabla_w^2 f_{\text{SCP}}(\bar{w}; \bar{w}) = B_{\text{GGN}}(\bar{w}) = \nabla_w^2 f_{\text{GGN}}(\bar{w}; \bar{w})$ 

Note: in general  $B_{\text{GGN}}(\bar{w}) \neq \nabla^2 f(\bar{w})$ 

### Main Theorem 1 [Diehl and Messerer, CDC 2019]

Regard  $w^*$  with  $\nabla f(w^*) = 0$  and  $B_{\text{GGN}}(w^*) \succ 0$ . Then

- $\hfill\blacksquare w^*$  is a fixed point for both the SCP and GGN iterations
- $\hfill$  both methods are well-defined in a neighborhood of  $w^*$
- their linear contraction rates are equal and given by the LMI

 $\min\{\alpha \in \mathbb{R} \mid -\alpha B_{\text{GGN}}(w^*) \preceq E_{\text{GGN}}(w^*) \preceq \alpha B_{\text{GGN}}(w^*)\}$ 

### Main Theorem 1 [Diehl and Messerer, CDC 2019]

Regard  $w^*$  with  $\nabla f(w^*) = 0$  and  $B_{\text{GGN}}(w^*) \succ 0$ . Then

- $\blacksquare w^*$  is a fixed point for both the SCP and GGN iterations
- $\hfill$  both methods are well-defined in a neighborhood of  $w^*$
- their linear contraction rates are equal and given by the LMI

$$\min\{\alpha \in \mathbb{R} \mid -\alpha B_{\text{GGN}}(w^*) \preceq E_{\text{GGN}}(w^*) \preceq \alpha B_{\text{GGN}}(w^*)\}$$

Corollary: Necessary condition for local convergence of both methods is

$$B_{\rm GGN}(w^*) \succeq \frac{1}{2} \nabla^2 f(w^*) \succeq 0$$

16/42

### Main Theorem 1 [Diehl and Messerer, CDC 2019]

Regard  $w^*$  with  $\nabla f(w^*) = 0$  and  $B_{\text{GGN}}(w^*) \succ 0$ . Then

- $\hfill\blacksquare w^*$  is a fixed point for both the SCP and GGN iterations
- $\hfill$  both methods are well-defined in a neighborhood of  $w^*$
- their linear contraction rates are equal and given by the LMI

$$\min\{\alpha \in \mathbb{R} \mid -\alpha B_{\text{GGN}}(w^*) \preceq E_{\text{GGN}}(w^*) \preceq \alpha B_{\text{GGN}}(w^*)\}$$

Corollary: Necessary condition for local convergence of both methods is

$$B_{\rm GGN}(w^*) \succeq \frac{1}{2} \nabla^2 f(w^*) \succeq 0$$

\*Proof of corollary: Set  $\alpha = 1$  and use  $E_{\text{GGN}}(w^*) = \nabla_w^2 f(w^*) - B_{\text{GGN}}(w^*)$ 

Define solution operators  $w^{\rm sol}_{\rm SCP}(\bar{w})$  and  $w^{\rm sol}_{\rm GGN}(\bar{w})$  at linearization point  $\bar{w}$  and apply the implicit function theorem to

$$abla_w f_i(w_i^{\text{sol}}(\bar{w}); \bar{w}) = 0 \quad \text{for} \quad i = \text{SCP}, \text{GGN}$$

Well-defined for  $\bar{w}$  in neighborhood of  $w^*$  because  $\nabla^2_w f_{\rm SCP}(w^*;w^*) = \nabla^2_w f_{\rm GGN}(w^*;w^*) = B_{\rm GGN}(w^*) \succ 0$ , and derivatives are given by

$$\frac{\mathrm{d}w_i^{\mathrm{sol}}}{\mathrm{d}\bar{w}}(w^*) = -(\underbrace{\nabla_w \nabla_w f_i(w^*;w^*)}_{=B_{\mathrm{GGN}}(w^*)=:B_*})^{-1}\underbrace{\nabla_{\bar{w}} \nabla_w f_i(w^*;w^*)}_{=E_{\mathrm{GGN}}(w^*)=:E_*}$$

We used that all second derivatives are equal due to Lemma 3 and that

$$\nabla_{\bar{w}} \nabla_w f_{\text{GGN}}(w^*; w^*) = \nabla_{\bar{w}} \left( \nabla f(\bar{w}) + B_{\text{GGN}}(\bar{w})(w - \bar{w}) \right) \Big|_{w = \bar{w} = w^*}$$
$$= \nabla^2 f(w^*) - B_{\text{GGN}}(w^*) = E_{\text{GGN}}(w^*)$$

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □

Spectral radius  $\rho(-B_*^{-1}E_*) = \rho(B_*^{-1}E_*)$  equals linear contraction rate of SCP and GGN algorithms. Matrix can be transformed to similar, but symmetric matrix:  $B_*^{-1}E_* \sim B_*^{-\frac{1}{2}} E_* B_*^{-\frac{1}{2}}$  with same spectral radius.

Now, 
$$\rho(B_*^{-\frac{1}{2}} E_* B_*^{-\frac{1}{2}}) \leq \alpha \quad \Leftrightarrow \quad -\alpha I \preceq B_*^{-\frac{1}{2}} E_* B_*^{-\frac{1}{2}} \preceq \alpha I$$
  
 $\Leftrightarrow \quad -\alpha B_* \preceq E_* \preceq \alpha B_* \quad \Box$ 

SCP and GGN do not converge to every local minimum. This can help to avoid "bad" local minima, as discussed next.

Regard maximum likelihood estimation problem  $\left[\min_w \phi(M(w) - y)\right]$ with nonlinear model  $M : \mathbb{R}^n \to \mathbb{R}^N$  and measurements  $y \in \mathbb{R}^N$ . Assume penalty  $\phi$  is symmetric with  $\phi(-z) = \phi(z)$  as is the case for symmetric error distributions. At a solution  $w^*$ , we can generate "mirror measurements"  $y_{\mathrm{mr}} := 2M(w^*) - y$  obtained by reflecting the residuals. From a statistical point of view,  $y_{\mathrm{mr}}$  should be as likely as y.

# SCP Divergence $\Leftrightarrow$ Minimum unstable under mirroring

#### Theorem 2 [Diehl and Messerer 2019] generalizing [Bock 1987]

Regard a local minimizer  $w^*$  of  $f(w) = \phi(M(w) - y)$  with  $\nabla^2 f(w^*) \succ 0$ . If the necessary SCP-GGN-convergence condition  $B_{\rm GGN}(w^*) \succeq \frac{1}{2} \nabla^2 f(w^*)$  does not hold, then  $w^*$  is a stationary point of the mirror problem but **not** a local minimizer.

# SCP Divergence $\Leftrightarrow$ Minimum unstable under mirroring

#### Theorem 2 [Diehl and Messerer 2019] generalizing [Bock 1987]

Regard a local minimizer  $w^*$  of  $f(w) = \phi(M(w) - y)$  with  $\nabla^2 f(w^*) \succ 0$ . If the necessary SCP-GGN-convergence condition  $B_{\rm GGN}(w^*) \succeq \frac{1}{2} \nabla^2 f(w^*)$  does not hold, then  $w^*$  is a stationary point of the mirror problem but **not** a local minimizer.

\*Sketch of proof: use 
$$M(w^*) - y_{mr} = y - M(w^*)$$
 to show that  $\nabla f_{mr}(w^*) = J(w^*)^\top (y - M(w^*)) = 0$  and  $\nabla^2 f_{mr}(w^*) = B_{GGN}(w^*) - E_{GGN}(w^*) = 2B_{GGN}(w^*) - \nabla^2 f(w^*) \not\geq 0$ 

20 / 42

## Illustrative example (experiments conducted by Florian Messerer)

Regard scalar model with unknown parameter w

$$m(x,w) := \sin(wx)$$

with input output measurements  $(x_i, y_i)$  for i = 1, ..., N (left plot). Define  $M_i(w) := m(x_i, w)$  and F(w) := M(w) - yAs outer convexity we use a Huber-like penalty (right plot)

$$\phi(z) := \frac{1}{N} \sum_{i=1}^{N} \sqrt{\delta^2 + z_i^2},$$
(3)

21/42

## Implementation of SCP and GGN

- obtain all needed derivatives from CasADi via MATLAB interface
- use linear solve ("backslash") for GGN
- formulate SCP subproblem as second order cone program (SOCP):

$$\begin{array}{ll} \min\limits_{\substack{w \in \mathbb{R}, \\ s \in \mathbb{R}^N}} & \sum\limits_{i=1}^N s_i \\ \text{s.t.} & \sqrt{\delta^2 + F_{\text{lin},i}(w;w_k)^2} \le s_i \quad \text{for } i = 1, \dots, N \end{array}$$

use Gurobi via CasADi as SOCP solver

# CasADi for Optimization Modelling

http://casadi.org

- · A software framework for nonlinear optimization and optimal control
- · "Write an efficient optimal control solver in a few lines"
- Implements automatic differentiation (AD) on sparse matrix-valued computational graphs in C++11
- · Front-ends to Python, Matlab and Octave
- · Supports C code generation
- Back-ends to SUNDIALS, CPLEX, Gurobi, qpOASES, IPOPT, KNITRO, SNOPT, SuperSCS, OSQP, ...
- · Developed by Joel Andersson and Joris Gillis

## Empirical Contraction Rates in Agreement with Theorem 1

 $\kappa_k =$ 

# Iteration count: SCP more predictable than GGN

27 / 42

# Overview

## Smooth unconstrained problems

- Sequential Convex Programming (SCP)
- Generalized Gauss-Newton (GGN)
- Local convergence analysis
- Desirable divergence
- Illustrative example in CasADi
- Constrained problems
  - Sequential Convex Programming (SCP)
  - Sequential Linear Programming (SLP)
  - Constrained Generalized Gauss-Newton (CGGN)
  - Sequential Convex Quadratic Programming (SCQP)
- Recent Progress in Dynamic Optimization and Applications

# Sequential Convex Programming (SCP)

$$\begin{array}{ll} \underset{w \in \mathbb{R}^{n_w}}{\text{minimize}} & \phi_0(F_0^{\text{lin}}(w; \bar{w}))\\ \text{subject to} & F_i^{\text{lin}}(w; \bar{w}) \in \Omega_i, \quad i = 1, \dots, m,\\ & G^{\text{lin}}(w; \bar{w}) = 0 \end{array}$$

• obtain  $w_{k+1}$  as solution of convex problem at  $\bar{w} = w_k$ 

• only primal variables  $\overline{w}$  form "optimizer state", no multipliers needed • SCP is affine invariant

## From now on assume more smoothness and regard a smooth NLP

$$\begin{array}{ll} \underset{w \in \mathbb{R}^{n_w}}{\text{minimize}} & \underbrace{\phi_0(F_0(w))}_{=:f_0(w)} \\ \text{subject to} & \underbrace{\phi_i(F_i(w))}_{=:f_i(w)} \leq 0, \quad i = 1, \dots, m, \\ & G(w) = 0 \end{array}$$

30 / 42

with convex  $C^2$  functions  $\phi_0, \phi_1, \ldots, \phi_m$ .

# Sequential Linear Programming (SLP)

If functions  $\phi_0, \ldots, \phi_m$  are linear, SCP just solves linear programs (LP):

$$\begin{array}{ll} \underset{w \in \mathbb{R}^{n_w}}{\text{minimize}} & f_0^{\text{lin}}(w; \bar{w}) \\ \text{subject to} & f_i^{\text{lin}}(w; \bar{w}) \leq 0, \quad i = 1, \dots, m, \\ & G^{\text{lin}}(w; \bar{w}) = 0 \end{array}$$

- might be called Sequential Linear Programming (SLP)
   ("Method of Approximation Programming" by Griffith & Stewart, 1961)
- equivalent to standard SQP with zero Hessian
- SLP only attracted to NLP solutions in vertices of feasible set
- works very well for L1-estimation [Bock, Kostina, Schlöder 2007]
- converges quadratically once correct active set is discovered

# Picture from Griffith and Stewart's original 1961 paper

# Constrained Generalized Gauss-Newton [Bock 1987]

Use  $B_{\rm GGN}(w) := J_0(w)^\top \nabla^2 \phi_0(F_0(w)) J_0(w)$  and solve convex quadratic program (QP)

$$\begin{array}{ll} \underset{w \in \mathbb{R}^{n_w}}{\text{minimize}} & f_0^{\text{lin}}(w; \bar{w}) + \frac{1}{2} (w - \bar{w})^\top B_{\text{GGN}}(\bar{w}) (w - \bar{w}) \\ \text{subject to} & f_i^{\text{lin}}(w; \bar{w}) \le 0, \quad i = 1, \dots, m, \\ & G^{\text{lin}}(w; \bar{w}) = 0 \end{array}$$

like SCP, the method is multiplier free

also affine invariant

Remark: for least-squares objectives, this method is due to [Bock 1987]. In mathematical optimization papers, Bock's method is called "the Generalized Gauss-Newton (GGN) method" because it generalizes the GN method to constrained problems. To avoid a notation clash with computer science we prefer to call Bock's method "the Constrained Gauss-Newton (CGN) method".

$$B_{\text{SCQP}}(w,\mu) := J_0(w)^\top \nabla^2 \phi_0(F_0(w)) J_0(w) + \sum_{i=1}^m \mu_i J_i(w)^\top \nabla^2 \phi_i(F_i(w)) J_i(w)$$

$$\begin{array}{ll} \underset{w \in \mathbb{R}^{n_w}}{\text{minimize}} & f_0^{\text{lin}}(w; \bar{w}) + \frac{1}{2} (w - \bar{w})^\top B_{\text{SCQP}}(\bar{w}, \bar{\mu}) (w - \bar{w}) \\ \text{subject to} & f_i^{\text{lin}}(w; \bar{w}) \le 0, \quad i = 1, \dots, m, \quad | \quad \mu^+, \\ & G^{\text{lin}}(w; \bar{w}) = 0 \end{array}$$

- again, only a QP needs to be solved in each iteration
- again, affine invariant
- $\blacksquare$  "optimizer state" contains both,  $\bar{w}$  and inequality multipliers  $\bar{\mu}$
- $B_{SCQP}(w, \mu) \succeq B_{GGN}(w)$  i.e. more likely to converge than GGN
- SCQP has same contraction rate as SCP, characterized by two LMI on the reduced Hessian approximation [Messerer &D., 2019]

## Dynamic Optimization in a Nutshell

minimize  

$$\begin{array}{ll}
\text{minimize} & \sum_{i=0}^{N} \varphi_i(F_i(x_i, u_i)) + \varphi_N(F_N(x_N)) \\
\text{subject to} & x_{i+1} = S_i(x_i, u_i), \quad i = 0, \dots, N-1, \\
& H_i(x_i, u_i) \in \Omega_i, \quad i = 0, \dots, N-1, \\
& H_N(x_N) \in \Omega_N
\end{array}$$

• variables w = (x, u) with  $x = (x_0, \ldots, x_N)$  and  $u = (u_0, \ldots, u_{N-1})$ 

- convexities in  $\varphi_i$  (e.g. quadratic) and  $\Omega_i$  (e.g. polyhedral)
- nonlinearities in dynamic system  $S_i$  and constraint functions  $F_i$ ,  $H_i$
- often:  $S_i$  result of time integration (direct multiple shooting)

# Conclusions

- Discussed a family of Iterative Convex Approximation Methods
- Sequential Convex Programming (SCP) conceptually simplest ("linearize nonlinearities, keep all convex structures") and most widely applicable e.g. to nonlinear cone programming.
- Generalized Gauss-Newton (GGN) cheaper iterations as only QPs are solved. Unconstrained GGN and constrained SCQP show identical local convergence rates as SCP for smooth problems.
- Local contraction rate for both SCP and GGN equals smallest  $\alpha$ satisfying  $-\alpha B_{\text{GGN}}(w^*) \preceq \nabla^2 f(w^*) - B_{\text{GGN}}(w^*) \preceq \alpha B_{\text{GGN}}(w^*)$
- Divergence might in fact be a desirable property in estimation as it avoids being attracted by statistically unstable local minima
